Legal perspectives on inflation: Implications for economic growth in 45 nations

Quan điểm pháp luật về lạm phát: Ý nghĩa tới tăng trưởng kinh tế ở 45 quốc gia

Abstract: Inflation, a phenomenon with far-reaching social and economic implications, has gained heightened attention in the wake of the COVID-19 pandemic, prompting global scrutiny. This study examines the current state of inflation across 45 nations and reevaluates its interplay with economic growth, focusing on the years 2010 through 2021. Utilizing methodologies including Ordinary Least Squares (OLS), fixed effects, and random effects models, we analyze the legal ramifications of inflation on economic development and discern disparities between developed and developing jurisdictions. The goal of the study is to investigate the current state of global inflation and its relationship to economic development using a sample of 45 nations for the years 2010 through 2021. Our findings underscore the dual impact of inflation on economic growth, with implications for legal frameworks and regulatory approaches. There was a negative impact of inflation on the economic growth in both 45 countries and each group of countries in the period from 2010 to 2021. In contrast, inflation remained positive with economic growth during the COVID-19 pandemic period from 2019 to 2021. The motivation of this research paper is to fill the gap with previous studies, providing an overview and more objective results for the inflation situation as well as its impact on economic growth.

Keywords: *COVID-19; Developed countries; Developing countries; Inflation; Economic growth.*

Tóm tắt: Lạm phát, một hiện tượng có ý nghĩa kinh tế và xã hội sâu rộng, đã thu hút được nhiều sự chú ý sau đại dịch COVID-19, khiến toàn cầu phải giám sát chặt chẽ. Nghiên cứu này xem xét tình trạng lạm phát hiện tại ở 45 quốc gia và đánh giá lại mối tương tác của nó với tăng trưởng kinh tế, tập trung vào các năm từ 2010 đến 2021. Bằng cách sử dụng các phương pháp bao gồm Bình phương tối thiểu thông thường (OLS), mô hình hiệu ứng cố định và hiệu ứng ngẫu nhiên, chúng tôi phân tích các tác động pháp lý lạm phát đối với sự phát triển kinh tế và phân biệt sự khác biệt giữa các khu vực pháp lý phát triển và đang phát triển. Mục tiêu của nghiên cứu này là điều tra tình trạng lạm phát toàn cầu hiện nay và mối quan hệ của nó với phát triển kinh tế bằng cách sử dụng mẫu gồm 45 quốc gia trong các năm từ 2010 đến 2021. Phát hiện của chúng tôi nhấn mạnh tác động kép của lạm phát đối với tăng trưởng kinh tế, cùng với những tác động đối với khuôn khổ pháp lý và các phương pháp điều tiết. Lạm phát có tác động tiêu cực đến tăng trưởng kinh tế ở cả 45 quốc gia và từng nhóm quốc gia trong giai đoạn 2010-2021. Ngược lại, lạm phát vẫn dương với tăng trưởng kinh tế trong giai đoạn đại dịch Covid-19 từ 2019 đến 2021. Mục đích của bài nghiên cứu này là nhằm lấp đầy khoảng trống với các nghiên cứu trước đây, đưa ra những kết quả tổng quan và khách quan hơn về tình hình lạm phát cũng như tác động của nó tới tăng trưởng kinh tế.

1. Introduction

Inflation has long been recognized as one of the most pressing issues facing the global economy, and concerns about its potential impact on economic growth have continued to be a topic of debate. Inflation has been linked to a range of factors, such as changes in interest rates, unemployment, and foreign direct investment (FDI). Understanding the relationship between inflation and economic growth is critical for economists, researchers, and policymakers. As a result, a large body of literature has examined the impact of inflation on economies as well as economic growth.

In recent years, many countries have experienced moderate inflation levels, driven by various factors such as supply chain disruptions, higher commodity prices, and increased demand for goods and services. However, some countries have seen significantly higher levels of inflation. According to data from the World Bank, as of 2021, the countries with the highest inflation rates were Sudan (382.8%), Lebanon (154.8%), and Zimbabwe (98.5%). On the other hand, the countries with the lowest inflation rates were Chad (-0.8%), Bahrain (-0.6%), and Rwanda (-0.4%). The causes of inflation can vary depending on the specific economic conditions of a country, and the impact of inflation can have wide-ranging consequences for its economies, businesses, and citizens. There are several lines of literature that reflect the causes of inflation. Factors such as fiscal policy, monetary policy, exchange rate movements, supply shocks, structural factors [1], and changes in aggregate demand [2] can contribute to inflationary pressures in developing economies.

To examine the impact of inflation on economic growth, two competing hypotheses are developed. The first hypothesis argues that inflation has a potentially positive impact on economic growth [3] [4] [5] [6] [7] [8]. Using cointegration and error correction models, [9] found a positive long-run relationship between GDP growth rates and inflation, which results in moderate inflation being beneficial to growth and higher economic growth entails inflation. Moreover, a low but positive inflation rate can help overcome nominal rigidities, facilitate relative price adjustments, and provide flexibility in monetary. Conversely, the alternative hypothesis is that inflation has a negative impact on economic growth, and it outweighs any potential positive ones. High inflation rates hinder investment, reduce productivity, distort resource allocation and negatively affect. Inflation can exacerbate income inequality by eroding the purchasing power of lower-income groups and redistributing wealth towards those with more bargaining power. Furthermore, high inflation rates can lead to increased unemployment through various channels, such as wage-setting behavior, labor market frictions, and the impact on investment decisions [10]. It can be easily seen that the differences in economic theories, methodological approaches, and empirical data lead to the existence of competing hypotheses regarding the impact of inflation on economic growth. Hence, the complexity of the issue and the various factors that can influence the relationship were emphasized. Researchers use different theories,

methods, and data to investigate this relationship, leading to a range of findings in previous research. As a result, the debate continues among economists, policymakers, and academics regarding the precise nature and magnitude of the relationship between inflation and economic growth.

However, little is known about whether and how inflation today impacts economic growth. This research will fill the gap of former research as most of them ceased data of 2020 without the latest updated data, and they mainly focused on analyzing data in one country or several countries in the same region without wide-scaled comparison [3] [11] [8]. To test these hypotheses, we analyze the current situation in the world with data up to 2021 from 45 different countries, which are divided into groups of developed and developing countries. Besides, we will show the relationship between inflation and economic growth.

2021 has seen a number of upheaval events that could undermine the commonly documented relationship between inflation and economic growth. The most notable is the COVID-19 pandemic, dramatically affecting the global economy. Firstly, the pandemic caused disruptions in supply chains, causing shortages and higher prices for certain items, contributing to inflation. However, as the pandemic led to widespread economic shutdowns, the demand for goods and services decreased, leading to a deflationary impact on prices. The pandemic has caused a significant GDP drop and negatively affected economic growth. Governments worldwide have introduced different policies to boost their economies, including interest rate cuts and stimulus packages. Nonetheless, it is still uncertain how long and severe the pandemic's economic repercussions will be. The COVID-19 pandemic has significantly impacted inflation and economic growth, and it is still uncertain how long and how severe the effects will be. It is also unclear what strategies will be the most effective in reducing the impact.

Our study uses ordinary least squares (OLS), fixed effects, and random effects models to examine whether and how inflation has impacted economic growth. Using data from 45 countries worldwide, we documented that the coefficient of inflation impacts on GDP in 45 countries is negative in all cross-countries, developed and developing countries. Therefore, if inflation increases, economic growth will decrease and vice versa. In contrast, the subsample in the COVID-19 pandemic period from 2019 to 2021 showed a positive impact of inflation on economic growth, this is opposed to our previous findings. If inflation increases, economic growth will also develop and vice versa. Figure 1 shows the impacts of inflation on economic growth in the world context from the 2010-2021 period. In Figure 1, we can see positive and negative relationships between inflation and economic growth. The positive relationship is concisely shown in the year of 2012, 2015, 2017, 2019, 2020 and 2021 while the negative relationship occurred in the year of 2011, 2013, 2014, 2016 and 2018. The highest GDP and CPI figures are 5.87% and 4.82%, while the lowest GDP and CPI figures are -3.11% and 1.43%, respectively.

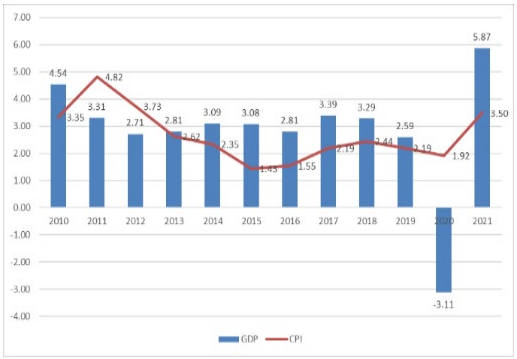

Fig. 1. The graph of the relationship between GDP and CPI on average in the world context from 2010-2021 (World Bank)

This study contributes to the extant literature that has broad implications for research on inflation and its relationship with economic growth. First, it provides new empirical evidence on the relationship between inflation and economic growth in a larger sample of 45 countries over the period 2010-2021, which are divided into two main groups of countries. Previous studies have often focused on a limited number of countries, which may not provide a representative picture of the global situation [12] [9] [11]. This study can provide a more comprehensive understanding of the relationship between inflation and economic growth by including many countries. Second, this research incorporates several control variables that may influence the relationship between inflation and economic growth, including inflation rate, unemployment rate, FDI, economic openness, lending rate, and population growth. By controlling for these factors, we can better isolate the effect of inflation on economic growth and provide more accurate estimates of its impact.

The remainder of this research paper is structured as follows: Section 2 reviews the literature and develops the hypothesis. Section 3 describes the data tables with variables and research methodology. Our findings and research results are provided in section 4. Finally, section 5 contains our summary and conclusions.

2. Literature review and hypothesis development

2.1. Literature review

According to the International Monetary Fund, inflation is the rate of price growth over a certain time. It generally refers to a broad metric, like the general rise in prices or the rise in a nation's cost of living. But it may also be reckoned more precisely for some products like food or services, like a hairstyle. Whatever the environment, inflation represents how much more precious the applicable set of goods and or services has become over a certain period. Believing that inflation is expensive, central bankers and most other observers see price stability as a worthwhile goal [3]. [13] suggested that policymakers need to be aware of when inflation starts to have a negative impact while [14] found a one-way causal link connecting inflation and economic growth.

The relationship between inflation and economic growth has already been analyzed in many previous research papers. Theoretically, inflation can affect economic growth on both sides, positively and negatively. High growth, lower inflation and lower inflation have made the economy grow. [15] applied the theoretical framework to show that inflation had a positive impact through precautionary savings in the short term. [16] stated that low inflation promotes high economic growth and that there is a positive relationship between inflation

uncertainty and economic growth [17]. The inflation rate below the examining threshold had a positive effect on growth, 3.89% of the inflation rate threshold was found in Malaysia [18], and 13% of the inflation rate threshold was examined in the case of Azerbaijan [19]. [20] has stated that sometimes there are positive impacts of GDP on the CPI if the impacts become stronger during the expansion phase. Therefore, a country can endure inflation at a certain level to obtain positive impacts on economic growth.

In contrast, inflation has a negative impact on economic growth and investment [3]. [21] also stated that inflation significantly negatively impacted economic growth for Asian countries. High inflation can cause a decrease in bank lending and return on real estate through real interest rates [13]. [14], who used the cointegration and causality test, bounds test and WALD test, have shown that there was a negative significant impact in the short term between real GDP and CPI variances. There is a detrimental inflation-growth impact, which is more pronounced at lower inflation rates. For the OECD nations, inflation had a considerable negative impact, and it was the same as that of the APEC countries [7]. In the threshold model, an inflation rate which is above the inflation rate threshold according to different countries or areas will have negative impacts on economic growth. A higher than 9% inflation rate has a detrimental effect on economic expansion [22], a rate of inflation exceeding 3.89% hurts economic expansion [18], and a inflation rate which is between 10 per cent to 20 per cent will have negative impacts on economic growth [4].

Moreover, it has also been proved that there is no significant relationship between inflation and economic growth. [23] used the nonlinear least square model (NLLS) to show that a threshold for an inflation rate of 1 to 3 per cent for developed nations and 7 to 11 per cent for developing nations was proposed. The economic growth was unaffected by percentages below the range and negatively affected by percentages beyond it. Opposite to inflation and growth theories, there was no relationship between inflation and growth in OECD countries [21] [14] has stated that inflation and economic growth have no significant long-term relationship in Turkey.

Previous researchers have used diverse methods, theories, and models to analyze the relationship among inflation, economic growth, and other variances. [13] and [15] applied the theoretical framework in their papers. [7] used cointegration, fixed and random effect methods with GDP at constant prices, the annual rate of inflation, and the ratio of gross domestic investment to GDP variances contributing to the research results. In addition, the threshold model was widely applied to most research to find the inflation rate threshold affecting economic growth. [19] used the threshold model to analyze real GDP per capita, CPI, and gross fixed capital formation variances, while [22] used real GDP, population growth, CPI, and investment growth rate variances. Otherwise, [14] applied the cointegration, causality, bounds, and WALD tests with real GDP and CPI variances.

2.2. Hypothesis development

Based on the above analysis, we propose the following hypothesis:

H1: There is a negative impact of inflation on economic growth.

H2: There is a positive impact of inflation on economic growth.

Some research shows that the relationship is damaging in countries that are not able to maintain price stability in the case of high inflation. However, these studies are generally based on the assumption that the relationship is linear. According to the research of [23], the relationship between economic growth and inflation is long-term. By analyzing the relationship between inflation and economic growth using the VECM model based on the push response function and the variance decomposition, [23] found a new inflation threshold for developing countries industrialized countries and suggested that if inflation exceeds this new threshold, it will have a negative impact on economic growth. We can say that high inflation will slow economic growth, or in other words, the change in inflation is higher than in economic growth. Specifically, the inflation threshold in developing countries is 11-12%/year; in industrial countries, it is about 1-3%/year.

The first hypothesis suggests that high levels of inflation negatively impact economic growth. Inflation erodes the purchasing power of consumers and reduces their disposable income, leading to decreased consumption. Furthermore, high inflation rates often create uncertainty and instability in the economy, discouraging long-term planning and investment. Contrary to the first hypothesis, the second hypothesis posits that moderate inflation can actually stimulate economic growth under certain circumstances. According to this view, a mild level of inflation encourages consumer spending as people tend to spend more today if they believe prices will rise in the future. This increased consumption can drive up demand and stimulate production, leading to economic growth. This hypothesis acknowledges that there is a threshold beyond which inflation becomes detrimental to economic growth but believes that a certain degree of inflation can be beneficial within that limit.

It is possible that an economy can experience low growth and high inflation. A situation with decreased economic growth and a rise in inflation can arise due to cost-push inflation. This type of inflation happens when prices increase due to rising costs, such as oil prices. As a result, businesses face higher costs, and individuals have less disposable income. This ultimately leads to a slow economy and high inflation, also referred to as stagflation.

Inflation is the gradual rise in the prices of goods and services. It is generally agreed that inflation has a negative impact on economic growth. According to Forbes, there are several ways in which inflation can hurt consumers and economic growth. Firstly, high inflation creates uncertainty in the economy, which makes it challenging for businesses to plan and invest for the long term. Secondly, high inflation reduces consumer purchasing power, which lowers the demand for goods and services. Thirdly, inflation may lead to a decrease in real income, which can lower the standard of living for people in the economy. Lastly, high

inflation can discourage foreign investment, resulting in a decline in the foreign exchange rate, affecting the balance of payments.

There are various perspectives on the impact of inflation on economic growth. Some argue that a moderate inflation level can positively affect economic growth. One way in which inflation can stimulate growth is through the wealth effect. When prices rise, the value of assets, such as stocks and real estate, also increases. This increase in wealth can lead to higher consumer spending and investment, which in turn fuels economic growth. Inflation can also incentivize borrowing and investment. When prices are expected to rise, individuals and businesses may be motivated to borrow money at lower interest rates to make purchases or investments before prices increase further. Increased borrowing and investment can spur economic activity and contribute to overall growth.

Furthermore, inflation can help facilitate necessary adjustments in wages and prices. In a dynamic economy, some sectors may need price and wage increases to maintain equilibrium. Inflation allows for these adjustments, which can help to reallocate resources more efficiently and improve productivity, leading to economic growth. Therefore, while moderate inflation can have positive effects on economic growth by stimulating consumer spending and investment and facilitating necessary adjustments, policymakers must manage inflationary pressures to avoid the detrimental effects of high inflation.

To summarize, a high level of inflation can have numerous adverse impacts on the economy's growth, including a decline in investments, a decrease in purchasing power, a reduced demand for products and services, a lower real income, and a drop in foreign investment. Leaders and decision-makers must take necessary steps to tackle inflation by implementing effective monetary and fiscal policies, essential in maintaining a stable economy that facilitates long-term growth.

3. Methodology

3.1. Data

The study uses a dataset of 195 countries from 2010 to 2021 obtained from World Development Indicators (WDI). We have selected 45 countries from this database with all the necessary data. This includes 35 developing countries and ten developed countries.

We follow [20] and [24] by defining the relationship between inflation (measured by CPI), unemployment (measured by unemployment rate) and economic growth (measured by GDP).

We found that numerous studies on economic growth have investigated FDI and trade openness. For instance, using data from Pakistan covering the years 1980–2011, [25] showed the adverse effects of trade openness and the positive impacts of foreign direct investment on economic growth. Furthermore, [25] three-variable model, which uses data from 86 nations, demonstrated that per capita income increase was adversely correlated with current population growth. The last independent variable we include in our research is population growth.

3.2. Methodology

To test the relationship between inflation and economic growth of 45 countries for

the period 2010-2021, we estimate the following regression:

$$GDP_{it} = \alpha + \beta_1 * CPI_{it} + \beta_2 * UR_{it} + \beta_3 * FDI_{it} + \beta_4 * TO + \beta_5 * LR + \beta_6 * PG_{it} + \varepsilon_{it} \quad (1)$$

Where i denotes countries, t denotes years, CPI denotes Consumer Price Index, UR denotes Unemployment Rate, FDI denotes Foreign Direct Investment, TO denotes Trade Openness, LR denotes Lending Rate, and PG denotes Population Growth.

Since GDP (Gross domestic product) is one of the most common measures used to assess the economic growth rate of a country at a given time, we choose GDP as the dependent variable. We include several control variables that can affect GDP. In particular, we use consumer price index (Consumer Price Index), measured by tracking the change in the prices of a fixed basket of goods and services; unemployment rate (Unemployment Rate), measured as the percentage of unemployed workers at 15 years of age and above over the population; foreign direct investment (Foreign Direct Investment), measured in USD and as a share of GDP; trade openness (Trade Openness), measured as the ratio of total trade to GDP; lending rate (Lending Rate), measured by the GDP deflator; and population growth (Population Growth), measured by the net recruitment rate of individuals to the population.

Following earlier research, we successfully incorporate various fixed effects into our model specification to help alleviate certain endogeneity problems. These fixed effects include country-fixed effects, region-fixed effects and country-group fixed effects. In general, these fixed effects models assist us in controlling for covariate variations in institutional quality between various years as well as unobserved variability that differs among nations and regions [18]. To reduce the simultaneous bias problem, we also delayed all right-side variables by one year in accordance with other research [27]. Finally, it is the error term and is clustered at the national level to account for the data's serial correlation.

Table 1. Variables used and expected signs based on the theories.

Dependant variable	Independent variables	Expected relationship based on the theories
Gross Domestic Product (GDP)	Consumer Price Index (CPI)	-
	Unemployment Rate (UR)	-
	Foreign Direct Investment (FDI)	+
	Trade Openness (TO)	+
	Lending Rate (LR)	-
	Population Growth (PG)	-

3.3. Descriptive statistics

Summary statistics of our sample are shown in Table 2. Specifically, Table 2 Panel A reports summary statistics by countries with the number of country-year observations, their mean value of GDP and CPI over the 2010-2021 period and the country group. Table 2 Panel A consists of 11 country-year observations, 45 unique countries, ten developed countries and 35 developing countries. According to the United Nations Organization, developed countries are those that have advanced economies, extensive technical infrastructure, and

high standards of living, while developing countries are those with an industrial base that is less developed and have Human Development Index (HDI), including high GDP, that is lower than those of developed countries. The highest average GDP belongs to China, with 7.26%, and the lowest average GDP belongs to Italy, with 0.04%. Nigeria had the highest CPI figure, 12.35%, and Argentina did not find any CPI data available during this period.

Next, we report the descriptive statistics of the main variables in our study for the whole sample in Table 1 Panel B, for two subsamples of developed countries and developing countries in Panel C and Panel D, respectively. Panel B presents the summary statistics of cross-countries output measures and country characteristics, and the sample consists of 530 country-year observations and 45 unique countries. The maximum GDP and CPI are 12.31982% and 18.31226%, while the minimum is -9.77299% and -1.14391%, respectively. Panel C presents the summary statistics of developed countries' output measures and country characteristics, and the sample consists of 118 country-year observations and ten unique countries. The maximum GDP and CPI are 14.51975% and 8.542933%, while the minimum is -6.8423% and -2.425265%, respectively. Panel D presents the summary statistics of developing countries' output measures and country characteristics, and the sample consists of 412 country-year observations and 35 unique countries. The maximum GDP and CPI are 11.64892% and 18.67773%, while the minimum is -9.94324% and -0.90042%, respectively.

Table 2. Sample Description

Panel A: Lists of Countries in the Research over the 2010-2021 period

No.	Country	Obs	ΔGDP	ΔCPI	Country group
1	Albania	11	2.58	2.08	Developing

4. Results and discussion

4.1. Underlying reason and Impact of recent Inflation rates

After many years remaining at very low or moderate levels, by the end of 2021, inflation, in the world context, has reached its highest level. This could be happening for two main reasons: the world economy is reopening rapidly, and energy prices are higher. First, economies in the world are rebounding. As soon as the COVID-19 pandemic restrictions are lifted, people have regained normal activities. They tend to buy more and spend a large amount of money that was suspended during the blockade. As a result, companies are having a hard time keeping up with the rapidly increasing demand as they restructure the supply chains hit hard by the pandemic. The challenges put pressure on companies that they would probably raise prices higher. Second, higher energy prices are pushing up inflation. The energy crisis came after a year of decline in coal, oil, and gas mining. Gas prices have tripled since the beginning of the year. Oil prices rose more than 40%, hitting their highest levels since 2014. Coal prices climbed about 60%. Energy scarcity, along with inflationary pressure when the consumer price index (CPI) skyrocketed, exerted a heavy impact on people's lives. The world has witnessed this in 2021, when most countries are embracing safe adaptation measures for the post-pandemic period9 and reopening their economies.

The impact of inflation on economic growth in 2021 has been mixed. On one hand, rising prices can increase business profits, leading to higher investment and job creation. Additionally, inflation can encourage consumers to make purchases sooner rather than later, stimulating economic activity. However, high and persistent inflation can also have negative consequences for economic growth. It can reduce consumer purchasing power and lead to lower investment and job creation as businesses become more cautious about spending. It can also lead to higher interest rates, making it more expensive for businesses and individuals to borrow money and invest.

4.2. Regression result

This session presents the results of our baseline model by running regression (1) with three-panel data techniques, including ordinary least squares (OLS), fixed effects, and random effects. Using different testing techniques helps to provide robustness to our findings. The details are shown in Table 3.

The results for cross-country analysis are presented in Table 3, with column (1) showing the result of the OLS model, column (2) showing the result of the fixed effects model and column (3) showing the result of the random effects model. We can see a sign that the inflation coefficient is consistently negative across models but the OLS model. The inflation coefficient is statistically significant when applied to the fixed and random effects models, but the OLS model shows an insignificant result. Moreover, our estimated inflation coefficient, as shown in Table 1, is negative. Therefore, there is a negative inflation-economic growth relationship [7] [3]. In conclusion, since inflation has a negative impact on economic growth in those countries, we deny H2 and accept H1.

While the FDI coefficient is consistently negative and statistically significant in all specifications, and the coefficient value is only around -0.003, it has a negative impact on economic growth. In contrast, our expected FDI

coefficient in Table 1 is positive, which contradicts our findings. The trade openness coefficient is not statistically significant in all specifications, implying that the trade openness indicator has no impact on economic growth in these countries. Population growth coefficient shows a positive result in all models and is also statistically significant in all models; therefore, population growth has a positive and significant impact on economic growth. In contrast, our expected population growth coefficient tended to be negative based on theories. The unemployment rate coefficient shows a low and negative value, and it is not statistically significant in all specifications, which means the unemployment rate has no impact on economic growth. Moreover, the lending rate coefficient also shows low and negative results, and it is also not statistically significant in all models; therefore, the lending rate does not impact economic growth in those countries.

Table 3. Results of Cross-countries Analysis

	GDP		
Model	**OLS model (1)**	**Fixed effects (2)**	**Random effects (3)**
CPI	0.030 (0.536)	-0.091** (0.020)	-0.081** (0.039)
FDI	-0.003*** (0.001)	-0.003*** (0.001)	-0.003*** (0.000)
TO	-0.001 (0.836)	-0.001 (0.584)	-0.001 (0.604)
PG	0.489*** (0.003)	0.439*** (0.001)	0.442*** (0.001)
UR	-0.000 (0.733)	-0.000 (0.896)	-0.0001 (0.881)
LR	0.000 (0.693)	-0.000 (0.793)	-0.0001 (0.845)

This table shows the relationship between GDP and other variables over cross-country through coefficient figures. The independent variable is GDP. The key variable is CPI; other control variables are FDI, TO, PG, UR and LR. All variables are defined in the Appendix. The figures in parentheses "()" imply the P-value of each variable. The symbols ***, ** and * indicate statistical significance at 1%, 5% and 10%, respectively.

4.3. Developed countries

This session presents the results of our baseline model by running regression (1) with three-panel data techniques, including ordinary least squares (OLS), fixed effects, and random effects. Using different testing techniques helps to provide robustness to our findings. The details are shown in Table 4.

The results for developed countries analysis are presented in Table 4, with column (1) showing the result of the OLS model, column (2) showing the result of the fixed effects model and column (3) showing the result of the random effects model. We can also see a sign that the inflation coefficient is consistently negative in all specifications, which has a negative impact on economic growth in developed countries. The inflation coefficient is statistically significant only when applied to the fixed effects model but also to the OLS and random effects model. In conclusion, inflation continues to have a negative impact on economic growth in developed countries, we deny H2 and accept H1.

The trade openness coefficient is consistently positive in all models and statistically significant in the OLS and fixed effects model but in the random effects model. Compared to Table 1, the trade openness coefficient follows our

expected relationship between trade openness and economic growth. The population growth coefficient continues to show positive results in all specifications, and its value ranges from 0.448 to 0.657 in developed countries. The population growth indicator is statistically significant in all specifications; therefore, population growth also maintained a positive and strong relationship with economic growth against our expectations. In addition, the lending rate coefficient shows positive results in all specifications, while it is statistically significant only in the OLS model but also in the fixed and random effects model. In this case, the lending rate has a positive impact on economic growth for developed countries, contrary to our expected relationship in Table 1.

Table 4. Results of Developed Countries Analysis

Model	GDP		
	OLS model (1)	Fixed effects (2)	Random effects (3)
CPI	-0.120 (0.425)	-0.380** (0.025)	-0.155 (0.319)
FDI	2.79e-12 (0.524)	1.75e-12 (0.684)	2.93e-12 (0.487)
TO	0.005** (0.013)	0.065*** (0.001)	0.007 (0.060)
PG	0.448*** (0.003)	0.657*** (0.001)	0.528*** (0.002)
UR	-0.004 (0.574)	-0.009 (0.379)	-0.009 (0.361)
LR	0.286*** (0.005)	0.101 (0.758)	0.214 (0.160)

This table shows the relationship between GDP and other variables in developed countries through coefficient figures. The independent variable is GDP. The key variable is CPI; other control variables are FDI, TO, PG, UR and LR. All variables are defined in the Appendix. The figures in parentheses "()" imply the P-value of each variable. The symbols ***, ** and * indicate statistical significance at 1%, 5% and 10%, respectively.

4.4. Developing countries

This session presents the results of our baseline model by running regression (1) with three-panel data techniques, including ordinary least squares (OLS), fixed effects, and random effects. Using different testing techniques helps to provide robustness to our findings. The details are shown in Table 5.

The results for developing countries analysis are shown in Table 5, column (1) showing the result of the OLS model, column (2) showing the result of the fixed effects model and column (3) showing the result of the random effects model. We continue to see the negative values of the inflation coefficient ranging from -0.059 to -0.168. Except for the OLS model, the inflation coefficient is statistically significant in both fixed and random effects models. We can conclude that inflation has a negative impact on economic growth in developing countries following our expectation in Table 1. In conclusion, inflation maintains a negative relationship with economic growth in developing countries, so we deny H2 and accept H1.

The FDI coefficient is a sign of a negative impact on economic growth, and its value ranges from -1.82e-11 to -1.93e-11. As with the inflation coefficient, the FDI coefficient is statistically significant in fixed and random effects models and OLS models. In this case, FDI has a negative impact on economic growth in developing

countries, contrary to our expected positive result in Table 1. The trade openness coefficient shows positive figures, and it is statistically significant in all specifications, with values ranging from 0.009 to 0.015. Therefore, trade openness positively indicates economic growth in developing countries following our expectations. As the same with trade openness, population growth coefficient also shows positive results. Its value is high and ranges from 0.745 to 0.852, and the population growth coefficient is statistically significant in all models. Therefore, population growth also maintains a strong and positive relationship with economic growth in developing countries, which is against our expected negative relationship in Table 1.

Table 5. Result of Developing Countries Analysis

	GDP		
Model	**OLS model (1)**	**Fixed effects (2)**	**Random effects (3)**
CPI	-0.059 (0.239)	-0.168*** (0.000)	-0.136*** (0.002)
FDI	-1.82e-11 (0.054)	-1.93e-11*** (0.010)	-1.90e-11*** (0.017)
TO	0.015*** (0.008)	0.009** (0.038)	0.011** (0.023)
PG	0.852*** (0.000)	0.745*** (0.000)	0.775*** (0.000)
UR	-0.000 (0.762)	0.000 (0.958)	-0.000 (0.950)
LR	-0.002 (0.207)	-0.002 (0.193)	-0.002 (0.200)

This table shows the relationship between GDP and other variables in developing countries through coefficient figures. The independent variable is GDP. The key variable is CPI, and other control variables are FDI, TO, PG, UR and LR. All variables are defined in the Appendix. The figures in parentheses "()" imply the P-value of each variable. The symbols ***, ** and * indicate statistical significance at 1%, 5% and 10% levels, respectively.

4.5. Subsample of COVID-19 pandemic period (2019-2021)

This session presents the results of our baseline model by running regression (1) with three-panel data techniques, including ordinary least squares (OLS), fixed effects, and random effects. Using different testing techniques helps to provide robustness to our findings. The details are shown in Table 6.

The results for cross-countries in the COVID-19 pandemic period are shown in Table 6, with column (1) showing the result of the OLS model, column (2) showing the result of the fixed effects model and Column (3) showing the result of the random effects model. We can see the change in the relationship between inflation and economic growth. The inflation coefficient shows positive figures in all specifications, ranging from 0.509 to 0.933. Moreover, the inflation coefficient is statistically significant in all models, so inflation has a tremendous and positive impact on economic growth [15] [17] during the COVID-19 pandemic period, which is against our negative expectation in Table 1. This positive relationship was also clearly shown in Figure 1, which means an inflation increase would benefit economic growth in this period. Since inflation has a positive impact on economic growth, we accept H2 and deny H1.

The trade openness coefficient is positive and statistically significant in the fixed effects model and the OLS and random effects model. In this period, trade openness has a positive impact on economic growth. Compared to Table 1, the trade openness coefficient satisfies our expected positive relationship between trade openness and economic growth based on theories.

Table 6. Result of Cross-countries in the COVID-19 pandemic period (2019 - 2020)

	GDP		
Model	**OLS model (1)**	**Fixed effects (2)**	**Random effects (3)**
CPI	0.509*** (0.003)	0.933*** (0.002)	0.509*** (0.002)
FDI	-2.14e-11 (0.092)	-1.46e-11 (0.367)	-2.14e-11 (0.089)
TO	0.002 (0.724)	0.404*** (0.000)	0.002 (0.724)
PG	-0.299 (0.523)	0.261 (0.757)	-0.299 (0.522)
UR	-0.017 (0.214)	-0.011 (0.742)	-0.017 (0.211)
LR	2.01e-06 (0.446)	-2.62e-06 (0.561)	2.01e-06 (0.444)

This table shows the relationship between GDP and other variables in the COVID-19 pandemic period from 2019 to 2020 through coefficient figures. The independent variable is GDP. The key variable is CPI, and other control variables are FDI, TO, PG, UR and LR. All variables are defined in the Appendix. The figures in parentheses "()" imply the P-value of each variable. The symbols ***, ** and * indicate statistical significance at 1%, 5% and 10% levels, respectively.

5. Conclusion

5.1. Discussion and Conclusion

Inflation has long been a topic of interest, especially in the context of the covid 19 pandemic and the period of economic recovery. This study examines the context of inflation and its impact on the economic growth of 45 different countries around the world in the period 2010-2021 by applying Ordinary least squares (OLS), fixed effects and random effects models to analyze the theoretical content and the influence of variables: inflation rate, unemployment rate, FDI, trade openness, lending rate, and population growth. Empirical results show that inflation has a negative impact on economic growth, in which developed countries tend to be more severely affected.

Compared with our expected relationship between GDP and other variables in Table 1, our findings do not always follow precisely as theories. In the period from 2010 to 2021, while inflation and trade openness figures follow the expected relationship based on theories, FDI, population growth, and lending rate figures show the opposite side. The FDI coefficient showed negative results instead of positive ones, as expected in cross-country and developing countries. In contrast, population growth has a positive impact on economic growth rather than a negative impact, as in theories in all analyses. The increase in lending rate is also expected to be negative for economic growth, but we found it positive in some while analyzing developed countries. In the COVID-19 pandemic period from 2019 to 2021,

inflation, in contrast, has a positive relationship with economic growth, which is not only against the expected relationship in theories but also against our previous findings. Inflation would be beneficial to economic growth in some ways to develop in this period.

In the period from 2010 to 2021, the world's economic growth has been undergoing negative effects from the inflation rate, especially in developed countries. This is not a good sign for the world economy because the inflation rate is getting higher due to multi-layered crises. Negative effects of inflation can lead to an increase in lending rates, low income, the imbalance between the rich and the poor and a heavy impact on a country's debt. Countries, organizations, and enterprises need to be aware of this situation and take precautions for the upcoming unexpected situation in the economy. Besides inflation, other factors significantly impact economic growth, such as FDI, trade openness and population growth. While the FDI factor seems to impact cross-country evidence, trade openness and population growth negatively tend to be more favourable for economic growth. In contrast, the unemployment rate and lending rate did not have much impact on economic growth in this period, but they are the factors which need to be paid attention to soon if the inflation rate keeps going higher.

In conclusion, inflation generally has a negative impact on economic growth in the period of 2010 - 2021. Developed countries tend to suffer heavier damage from inflation than developing ones. At this time, an increase in FDI did not benefit economic growth, while enhancing trade openness and population growth would contribute to the development of the economy. In contrast, there is also a positive relationship between inflation and economic growth occurring in the specific period of the COVID-19 pandemic (2019-2021). Inflation was preferred to increase for a country's economic growth in this time. In short, we can be more confident that inflation can negatively and positively affect economic growth.

5.2. Contributions and Implications of the Study

The motivation of this research paper is to fill the gap with previous studies, providing an overview and more objective results for the inflation situation as well as its impact on economic growth. The contribution of this study is quite significant. It provides empirical evidence in 45 countries around the world, from different regions rather than being limited like most studies, and we divide into two main groups of countries for a more comprehensive view. That evidence was collected between 2010 and 2021. A newer step forward is the variables we identified in the article: inflation rate, unemployment rate, FDI, trade openness, lending rate, and population growth, which will help to visualize clearly, more precisely, the impact of inflation.

5.3. Limitations and Future Research of the Study

While doing this study, some limitations need to be mentioned. First, although variance data is large and easy to collect, data from many countries was poorly updated and still lacked some variances. Therefore, it is impossible to compare inflation's effects on economic growth in

more countries and give better results. Second, the data has not been updated to 2022, which is not the closest to the current situation. In 2022, there seem to be more changes in the economy due to some unexpected situations occurring worldwide. This study would be more significant if the data were updated to the year of 2022. Contrary to this, selecting a time frame from 2010 to 2021 helps ensure the accuracy and relevance of the data. A worthy-mentioned world issue occurred in this period, known as the COVID-19 pandemic, which lasted from 2019 to 2021. Therefore, we prefer the period with data availability and worthy research. Lastly, while solving the data, it did not show the expected results at the first step. Therefore, the data had to be well-checked and clarified while trying more methods to solve the data.

In future research, the authors need to use more advanced methods to understand the effects of inflation and other factors on economic growth. Moreover, the data needs to be updated to the period between 2022-2023, when the world's economy seems to experience some unexpected situations due to multi-layered crises. On the other hand, the authors can research the factors affecting the inflation rate to understand inflation better and give concise solutions to reduce the inflation rate.

Acknowledgments

We would like to sincerely acknowledge Dr Le Thi Thu Huong and Ms Nguyen Thuy Trang, who gave us the most enthusiastic support with our research assignment. Thanks to your guidance, support, encouragement, and carefulness, we can complete our research and achieve the best result. Their feedback and suggestions inspired our idea and shaped our research method.

We also wish to acknowledge the authors of the research papers and articles for their valuable works referenced in our research and the Department of Science, Technology, and Development cooperation for your guidance in supporting us during the research period.

Finally, we would like to thank our colleagues and peers who have dedicated their valuable time and effort throughout the research process. Their contributions were significant in initiating the research idea and completing the research result. We are grateful to appreciate their willingness to experience this with us.
